Lecture - 17
Linear/Non -Linear Second Order BVPs

Hi, so we have discussed in the last class, about the finite difference schemes and the corresponding error estimates. So, let us proceed further little bit on that, with respect to the stability aspects. So, and then we generalise the second order method.

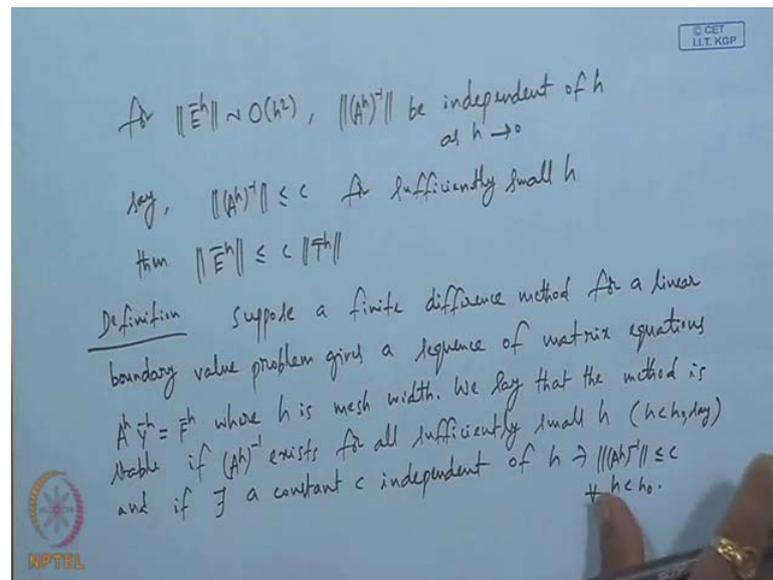

(Refer Slide Time: 00:40)

So, stability, consider so this equation so which we have derived so where A is the corresponding tri diagonal matrix and E is the error and error, global error matrix and then, this is the local truncation error matrix. So, this can be, this can be rewritten as A h, E h so this is just to know that for a specific h.

So, definitely the matrix A h so this is with h equals to 1 by and plus 1 for 0 1 case and the dimension of Ah, grows as this happens. Let Ah inverse exists, this implies Eh is then, the nor is equals to, but we have this, as order of h square. Therefore, we expect, we expect the same for. But, from this if you see for this, to have this order, this must be bounded by a constant.

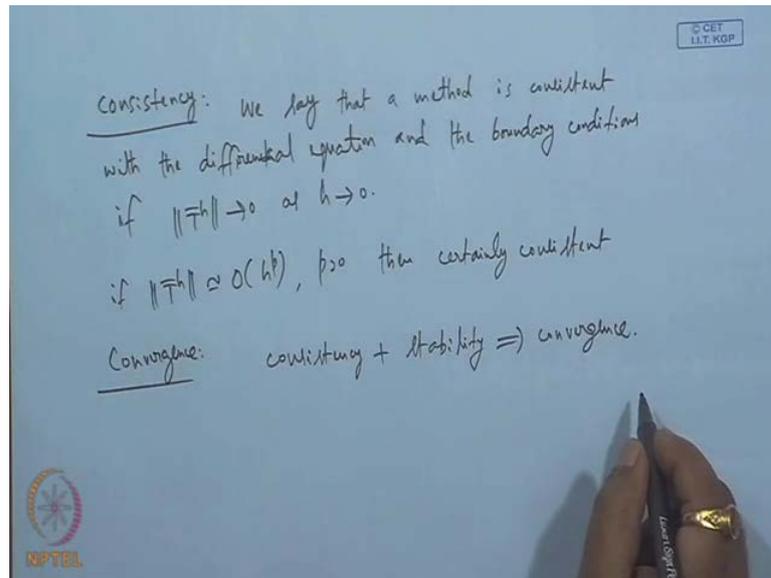

(Refer Slide Time: 03:41)

So, for this to behave in this order, this be independent of h as h goes to 0 say, less than or equals to c , for sufficiently small h then, we get. So, this suggests a definition that means so global error is bounded so we know local error is order of h square and global error is also bounded like that. Hence, the stability is ensured. Suppose a finite difference method, for a linear boundary value problem gives a sequence of matrix equations where, h is mesh width. We say that, the method is stable if this exists for all sufficiently small h so that is say h less than h naught say. And if there exists constant c , independent of h such that is less than equal to c , for every h . This is, this will suggest the stability condition.

So, once stability is done we need to, consistency so we have all talked before in the context of multi-step methods. So, we say that a method is consistent with the difference, method is consistent with the differential equation and boundary conditions, if the local truncation error goes to 0. As h goes to 0 and in general, this is order h power p , p greater than 0 then, then certainly consistent then what next, convergence.

(Refer Slide Time: 07:40)

So, since we talked on, with respect to multi step method I do not want to repeat just consistency plus stability implies convergence. So, with this we have some idea of really how a particular approximation is giving you sensible results. Because, you have taken a differential equation and then pick up the derivatives, approximate and then we try to solve system and get the corresponding solutions. But what kind of errors are introduced locally and then whether, really these errors are bounded so that globally the error is bounded.

So, they are not magnified so that, the method is stable. So, these on the conditions, on the matrix are really necessary. Now, let us we discussed earlier for a simple second order, that is $y'' = f(x)$. So, now let us generalise little bit more, where we have a general set up of linear second order boundary value problem.

(Refer Slide Time: 10:52)

Linear second order BVP

$$y'' + p(x)y' + q(x)y = r(x), \quad a < x < b \quad (1)$$

$$y(a) = \gamma_1; \quad y(b) = \gamma_2$$

$$y'_i = \frac{y_{i+1} - y_{i-1}}{2h} - \frac{h^2}{6} y'''(x_i)$$

$$y''_i = \frac{y_{i+1} - 2y_i + y_{i-1}}{h^2} - \frac{h^2}{12} y^{(4)}(x_i)$$

$x_{i-1} < x_i < x_{i+1}$

Second order BVP so we consider so this is our BVP, then the approximations. So, the first derivative is done with the central derivative approximations.

(Refer Slide Time: 12:29)

$$(1) \Rightarrow \frac{y_{i+1} - 2y_i + y_{i-1}}{h^2} + p(x_i) \frac{y_{i+1} - y_{i-1}}{2h} + q(x_i)y_i = r_i, \quad i = 1, \dots, N$$

$$y_0 = \gamma_1; \quad y_{N+1} = \gamma_2$$

$$y_{i+1} \left(1 + \frac{h}{2} p_i\right) + y_i \left(-2 + h^2 q_i\right) + y_{i-1} \left(1 - \frac{h}{2} p_i\right) = h^2 r_i$$

$$\Rightarrow A_i y_{i-1} + B_i y_i + C_i y_{i+1} = h^2 r_i$$

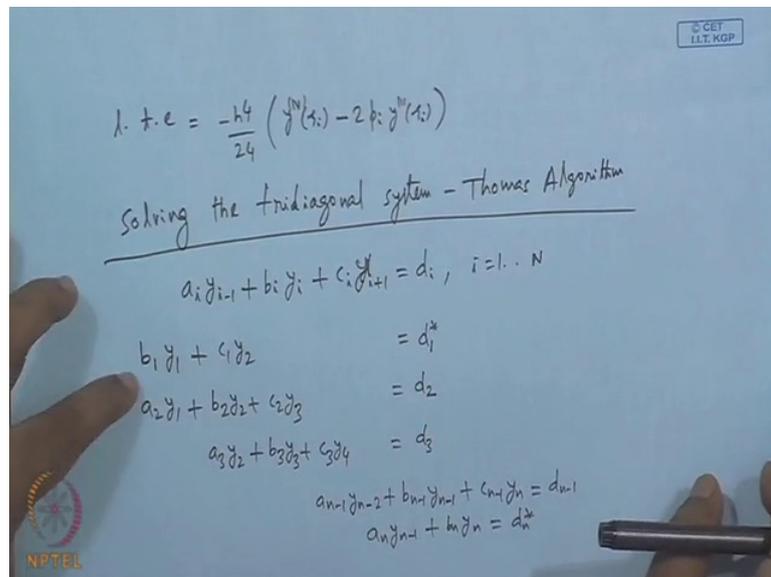

$$A_i = \left(1 - \frac{h}{2} p_i\right), \quad B_i = \left(-2 + h^2 q_i\right), \quad C_i = \left(1 + \frac{h}{2} p_i\right)$$

So, in view of this 1 becomes so y_0 is γ_1 and y_{N+1} is γ_2 . Now, we collect the coefficients of similar terms, so y_{i+1} , y_i , y_{i-1} so if you multiply by h^2 there so h gets cancelled, so $1 + \frac{h}{2} p$ and $-2 + h^2 q$ and $1 - \frac{h}{2} p$. So, this implies where so I started with y_{i-1} so this will come here.

Now with this set up we expect a tri diagonal system where, A is B1, C1. Because, when we run the system, when i is 1 y0 so A1 does not exist because, y0 is known to us. So, A1 gets transferred to the right hand side therefore, we have this. And similarly, when we run for i n so we have, when we run for i equals to n, we have n plus 1. So, this term gets transferred to the right hand side so we have, this is Bi so we have A and B.

So, and b bar look at that, when we run this for i equals to 1, h square r1 and y0 is gamma 1 so A1 gamma 1 gets transferred to the right hand side. So, we have h square r1 minus then we have h square r2, h square r3 then h square r n minus so i equals to n. So, this will be y n plus 1 so we have c n times gamma t.

(Refer Slide Time: 18:49)

So, this will be the tridiagonal system and the corresponding local truncation error. So, this will be the corresponding local truncation error so we have system like this. So, which is a tridiagonal system and the same can be solved solving the... So, generally it is an elimination process, but for this particular case since it is a tridiagonal. So, there is an algorithm called Thomas algorithm. So, let us look at it so let the given system be in this form. So, which means b1 y1 plus c1 y2 equals d1 star then a2 similarly, a3 y2 then n minus 1. So, this will like our tridiagonal system expansion.

(Refer Slide Time: 22:23)

assuming $b_1 \neq 0$, eliminate y_1 from the second eqn.

$$b_2' y_2 + c_2 y_3 = d_2' \quad \text{where}$$

$$b_2' = b_2 - \frac{a_2 c_1}{b_1}; \quad d_2' = d_2 - \frac{a_2 d_1}{b_1}$$

Next assume $b_2' \neq 0$, eliminate y_2 from the third eqn.

$$b_3' y_3 + c_3 y_4 = d_3' \quad \text{where}$$

$$b_3' = b_3 - \frac{a_3 c_2}{b_2'}; \quad d_3' = d_3 - \frac{a_3 d_2'}{b_2'}$$

Then, assuming b_1 is non-zero eliminate naturally y_1 , assuming b_1 non-zero we eliminate y_1 , from the second equation. So, we get b_2 prime that is modified b_2 is no longer b_2 , where b_2 prime is b_2 minus this. Next, assume b_2 prime non zero eliminate y_2 from the third equation of course, using this equation. Then we have v_3 prime y_3 , where.

(Refer Slide Time: 24:44)

we eliminate y_k at step k , from $(k+1)$ th eqn. ($b_k \neq 0$)

$$b_{k+1} y_{k+1} + c_{k+1} y_{k+2} = d_{k+1}$$

$$b_{k+1}' = b_{k+1} - \frac{a_{k+1} c_k}{b_k} \quad k = 1, 2, \dots, N-1$$

$$d_{k+1}' = d_{k+1} - \frac{a_{k+1} d_k'}{b_k}$$

back substitution at (k) , assuming $b_k \neq 0$, $y_N = \frac{d_N'}{b_N}$

and then for $k = N-1, \dots, 1$, $y_k = \frac{d_k' - c_k y_{k+1}}{b_k}$

So, we continue like this, we eliminate y_k at step k from k plus 1th equation of course, assuming this is non-zero, where k is. Now, what we have to do so having obtained up to

here, we back substitute, back substitution at n , assuming b_n prime non-zero, y_n is b_n prime.

And then, $1, y_k$ is so these are capital n we are using so this is Thomas algorithm. So, one can write a nice programme and then try to solve it so having done a linear system so the next task is to try out with a non-linear system. So, what is the big deal in it. Well, for the linear case we have obtained a system of equations and then it happened to be tridiagonal and then, we have a simple algorithm called Thomas algorithm.

And then one can obtain the solution, even otherwise using elimination etcetera. But in case of non-linear, one straight forward thing one could expect is, probably we expect that the system is non-linear so this is one thing. So maybe it is very trivial guess, but then the next task is how do we solve corresponding non-linear system of equations. So, let us look into non-linear system.

(Refer Slide Time: 28:30)

Non-linear second order BVP

$$y'' = f(x, y), \quad a < x < b \quad \text{--- (NL)}$$
$$y(a) = r_1; \quad y(b) = r_2$$
$$y_{i-1} - 2y_i + y_{i+1} = h^2 f(x_i, y_i)$$
$$y_0 = r_1; \quad y_{n+1} = r_2$$

NPTEL

So, non-linear second order BVP so we consider say so if we discretise, if we discretise. Now, as far as derivative is concerned it is linear, but we have the right hand side part is non-linear. So, let us see how this works out with reference to an example.

(Refer Slide Time: 30:09)

Example $y'' = xy' + x$, $y(-1) = 2$, $y(3) = -1$
 $h = 1$

$$y_{i-1} - 2y_i + y_{i+1} = x_i y_i^2 + x_i$$

$i=1$: $y_0 - 2y_1 + y_2 = 0$

$i=2$: $y_1 - 2y_2 + y_3 = y_2^2 + 1$

$i=3$: $y_2 - 2y_3 + y_4 = 2y_3^2 + 2$

-1	0	1	2	3
x_i	x_1	x_2	x_3	x_4
y_i	y_1	y_2	y_3	y_4 unknowns
2				-1

Suppose this is the example, I have taken h for simplicity, now the discretised version because, h is 1. So, this our grid, so essentially so these are the unknowns because, y_0 is 2, y_4 is minus 1. So, i equals to 1, x_0 , i equals to 1 so this will be x_1 , x_1 is 0 so unfortunately this is 0. So, this will be x_2 is 1 so this is 1 and y_2 square, so because x_3 is 2 so $2y_3$ square plus 2.

(Refer Slide Time: 33:14)

$$-2y_1 + y_2 + 2 = 0$$

$$\Rightarrow y_1 - 2y_2 + y_3 - y_2^2 - 1 = 0$$

$$y_2 - 2y_3 - 2y_3^2 - 3 = 0$$

$$\bar{F}(\bar{y}) = 0 = \begin{pmatrix} F_1(\bar{y}) \\ F_2(\bar{y}) \\ F_3(\bar{y}) \end{pmatrix} = \begin{pmatrix} -2y_1 + y_2 + 2 \\ y_1 - 2y_2 + y_3 - y_2^2 - 1 \\ y_2 - 2y_3 - 2y_3^2 - 3 \end{pmatrix} \text{--- (1)}$$

(1) is a non linear system of equations for y_1, y_2, y_3

Now, in this system these are known so the final system we get it as follows. If you observe I did not put this as a matrix system x equals to b because, this is a non-linear.

So, let us call this as f of y bar equals to 0, where we have as components of so that means this is, this is also vector. So, this is nothing but so these are our f_1, f_2, f_3 and what is it, is a non-linear system of equations for y_1, y_2 and y_3 . So, this is a non-linear system for y_1, y_2, y_3 .

So, how do we solve ((Refer time: 36:14)). So, I think you have heard for solving non-linear algebraic equations, we have lot of methods and one popular method is Newton Raphson method. Now for non-linear system, we should try Newton Raphson method. So, what is the motive?

(Refer Slide Time: 36:41)

Newton-Raphson's Method for solving Non-linear system

$F(\bar{y}) = 0$, expanding in Taylor-series about \bar{y}_i

$$\bar{F}(\bar{y}) = F(\bar{y}_i) + (\bar{y} - \bar{y}_i) \frac{\partial F}{\partial \bar{y}} + (\bar{y} - \bar{y}_i)^2 \frac{\partial^2 F}{\partial \bar{y}^2} + \dots = 0$$

$$= F(\bar{y}_i) + (\bar{y} - \bar{y}_i) \frac{\partial F}{\partial \bar{y}} + O(h^2) \approx 0$$

$$\Rightarrow \bar{y} = -F(\bar{y}_i) \left(\frac{\partial F}{\partial \bar{y}} \right)^{-1} + \bar{y}_i$$

$$\therefore \bar{y} = \bar{y}_i - F(\bar{y}_i) \left(\frac{\partial F}{\partial \bar{y}} \right)^{-1}$$

So, the motive behind so Newton Raphson's method for solving non-linear system, so what we have is this, suppose we expand in Taylors series about y_i plus. So, for a vector equation $dau f$ bar by $dau y$ bar so this is h square because, second order y minus y_i square. So, y bar is minus f of and this must be approximately 0, so this must be approximately 0. So, from here y bar I am retaining then, we must transfer these things, I am transferring this, but then this is a matrix. So, it becomes inverse there and minus y_i becomes this. So, therefore so this is now what is the inverse so this is the Jacobian $dau f$ by $dau y$ bar is the Jacobian and hence it is a inverse.

(Refer Slide Time: 40:16)

$$y^{(k+1)} = y^{(k)} - J^{-1}(y^{(k)}) F(y^{(k)})$$

$$J(y_1, y_2) = \frac{\partial F}{\partial y} \text{ Jacobian}$$

example

$$y'' = 9y^2 + \frac{1}{x}, \quad y(0) = 4, \quad y(1) = 1, \quad h = 1/3$$

$$x_0 = 0, \quad x_1 = \frac{1}{3}, \quad x_2 = \frac{2}{3}, \quad x_3 = 1$$

$$y_{i-1} - 2y_i + y_{i+1} = 9h^2 y_i^2 + \frac{h^2}{x_i^2}$$

$$y_0 = 4; \quad y_3 = 1.$$

So, accordingly the solution is an iterative method is defined so where the Jacobian. So, let us look at an example, let us look at an example, these are the boundary conditions. So, x_0 is 0, x_1 is one-third, two-third so the discretised version is. And we have y_0 and y_3 so we have y_0 is 4 and y_3 is 1.

(Refer Slide Time: 42:59)

$$\underline{i=1} \quad y_0 - 2y_1 + y_2 = y_1^2 + 1, \quad y_0 = 4$$

$$\underline{i=2} \quad y_1 - 2y_2 + y_3 = y_2^2 + \frac{1}{4}, \quad y_3 = 1$$

$$\Rightarrow \quad y_1^2 + 2y_1 - y_2 - 3 = 0 = f_1(y_1, y_2)$$

$$y_2^2 - y_1 + 2y_2 - \frac{3}{4} = 0 = f_2(y_1, y_2)$$

$$J(y_1, y_2) = \frac{\partial F}{\partial y} = \begin{pmatrix} \frac{\partial f_1}{\partial y_1} & \frac{\partial f_1}{\partial y_2} \\ \frac{\partial f_2}{\partial y_1} & \frac{\partial f_2}{\partial y_2} \end{pmatrix} = \begin{pmatrix} 2y_1 + 2 & -1 \\ -1 & 2y_2 + 2 \end{pmatrix}$$

So, let us run the system at i equals to 1 and i equals to 2 so we have y_0 is 4, 1. So, now it gets simplified, let us put it like this y_0 is 4 so it gets transferred. So, this is our, now we need to compute the Jacobian. So, this the Jacobian so in this case treating this as f

1th and this is f 2. So, this will be and with respect to 2 and here with respect 1, y1 and here so this a Jacobian.

(Refer Slide Time: 45:28)

$$J^{-1} = \frac{1}{D} \begin{pmatrix} 2y_2+2 & 1 \\ 1 & 2y_1+2 \end{pmatrix}, D = (2y_1+2)(2y_2+2) - 1 = 4(1+y_1)(1+y_2) - 1$$

$$\therefore \begin{pmatrix} y_1^{(k+1)} \\ y_2^{(k+1)} \end{pmatrix} = \begin{pmatrix} y_1^{(k)} \\ y_2^{(k)} \end{pmatrix} - \frac{1}{D^{(k)}} \begin{pmatrix} 2y_2^{(k)}+2 & 1 \\ 1 & 2(y_1^{(k)}+2) \end{pmatrix} \begin{pmatrix} f_1 \\ f_2 \end{pmatrix}$$

Need initial guess to start the iteration
Let $y_1^{(0)} = 2, y_2^{(0)} = 1$

Then, we need to compute this is, therefore, minus j inverse so where of course D is given by 2 y1. So, this is the iterative method now we have, we have to obtain y1 and y2 so this is Newton Raphson, need initial guess to start the iteration. So, let so let this be the initial guess.

(Refer Slide Time: 48:02)

$$f_1(y_1, y_2) = y_1^2 + 2y_1 - y_2 - 3 = 4 + 2 \times 2 - 1 - 3 = 8 - 4 = 4 \quad \begin{matrix} y_1^{(0)} = 2 \\ y_2^{(0)} = 1 \end{matrix}$$

$$f_2(y_1, y_2) = y_2^2 - y_1 + 2y_2 - \frac{3}{4} = 1 - 2 + 2 - \frac{3}{4} = \frac{1}{4}$$

$$D = 4(1+y_1)(1+y_2) - 1 = 4(1+2)(1+1) - 1 = 4 \times 3 \times 2 - 1 = 23$$

$$\begin{pmatrix} y_1^{(1)} \\ y_2^{(1)} \end{pmatrix} = \begin{pmatrix} 2 \\ 1 \end{pmatrix} - \frac{1}{23} \begin{pmatrix} 2(2)+2 & 1 \\ 1 & 2(3) \end{pmatrix} \begin{pmatrix} 4 \\ \frac{1}{4} \end{pmatrix}$$

$$= \begin{pmatrix} 2 \\ 1 \end{pmatrix} - \frac{1}{23} \begin{pmatrix} 4 & 1 \\ 1 & 6 \end{pmatrix} \begin{pmatrix} 4 \\ \frac{1}{4} \end{pmatrix} = \begin{pmatrix} 2 \\ 1 \end{pmatrix} - \frac{1}{23} \begin{pmatrix} \frac{65}{4} \\ \frac{14}{4} \end{pmatrix}$$

$$\approx \begin{pmatrix} 1.2065 \\ 0.9260 \end{pmatrix}$$

Then, f_1 this is, our guess was $y_1 = 0, y_2 = 0$ so this will be $4 + 2$ so $y_1^2 - 2 - 1 = 3$. So, this is 8 , this is 4 then, this will be y_2^2 , this will be y_2 , y_2 is 1 , that is correct.

So, $y_2^2 - y_1$ so $y_2^2 - y_1 + 2y_2$ so this will be $1 + 4$ and d so d was so this 4 into $1 + y_1$. So, $1 + 2 + 1 + 1$ so this will be 4 into 3 into 2 . So, accordingly $y_1 = 0, y_2 = 0$ minus 1 over D then, we need this terms two times $y_2 + 1$ so 2 times $y_2 + 1$ is $2 + 1 + 2$ times $y_1 + 1$. So, this multiplied by f_1, f_2 so here 4 and 1 on 4 so this is, so this is $2 + 1$ so you will get 16 plus and here we get so we can compute and we get some value. So I guess I have done it, but this is subject verification.

(Refer Slide Time: 52:36)

Handwritten mathematical work on a blue background showing the Newton-Raphson method for solving a system of equations. The work includes the Jacobian matrix J , the function values f_1 and f_2 at the initial guess $(y_1^{(0)}, y_2^{(0)}) = (0, 0)$, and the calculation of the next iteration $y^{(2)}$ using the inverse of the Jacobian matrix.

$$\begin{pmatrix} y_1^{(2)} \\ y_2^{(2)} \end{pmatrix} : \begin{aligned} f_1(y_1^{(0)}, y_2^{(0)}) &= 0.0426 \\ f_2(y_1^{(0)}, y_2^{(0)}) &= 0.3227 \\ J &= 15.1162 \end{aligned}$$

$$\begin{pmatrix} y_1^{(2)} \\ y_2^{(2)} \end{pmatrix} = \begin{pmatrix} 1.2065 \\ 0.3261 \end{pmatrix} = \frac{1}{15.1162} \begin{pmatrix} 3.152 & 1 \\ 1 & 4.417 \end{pmatrix} \begin{pmatrix} 0.0426 \\ 0.3227 \end{pmatrix}$$

$$= \begin{pmatrix} 1.1213 \\ 0.2172 \end{pmatrix}$$

So, then we have to iterate further $y_1 = 2$. So, in order to compute we need f_1 of so this probably, please verify there could be a mistake in the numerical calculation. Then the corresponding d and then so the other values so we may get some value. So, this the next iteration then, we continue further so we stop when we have decide accuracy.

So, essentially with respect to the Newton Raphson method, we are trying to solve the non-linear system and then, this is just a solution like this. So, may be while calculating this is 0 so throughout we have to multiply by the inverse. So, may be I made a mistake so this will come here so this is the linearization in some sense. So, the guess is correct when you have non-linear equation, remember the non-linearity is only with respect to right hand side not in the derivatives, so far.

So, if that is a case we get system of equations and then, in this case the corresponding system of equations are non-linear and we use Newton Raphson method to solve these non-linear system of equations. So, far the stories for a simple boundary conditions suppose, your boundary conditions involve derivatives. So for example, one can classify the boundary conditions like, if the function value is given say like, type and derivatives are type then, a combination is given then robin type.

So, if the derivatives are involved what would happen whether, the same techniques work well, the same techniques work, but the derivatives need to be discretised right. So, may be they will bring in little complications so we have to discuss them with a special care, so until then bye.
