Lecture - 7
Tutorial - 1

Hello good morning, so far we have learnt some single step methods to solve initial value problems. So, it would be better to work out some exercises in order to get the flavor of each of the methods and feel more confident.

(Refer Slide Time: 00:41)

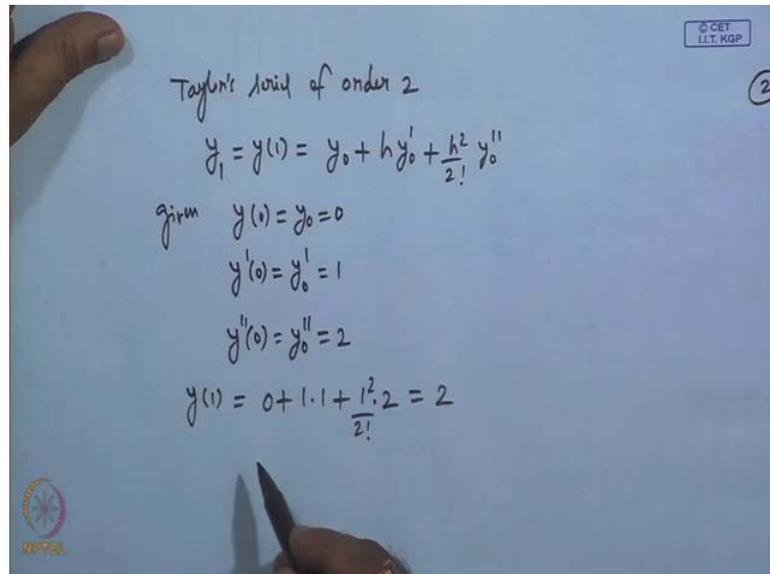

So, let us do some problems. This tutorial is on single step methods, so better to have your calculator with you and then start working with me. So, this is problem 1, compute an approximation to y of 1, y dash of 1 and y double dash of 1 using Taylor's series method of order 2 with h equals to 1, when y x is the solution of... So, let us read the problem carefully, compute an approximation to y of 1, y dash of 1 and y double dashed of 1 using Taylor's series method of order 2 with h equals to 1, when y axis the solution of the following initial value problem.

Look at that, this is the third order, so hence we have 1, 2, 3 initial conditions all at. So, we have x_0 is 0, h is 1, well I have taken h is 1 just for a computational e's. Now, we are asking to compute approximations for y of 1, which is y_1 , y dashed of 1 is y_1 dashed, y double of 1, so these are to be computed. So, it is to be computed using Taylor series

suppose, y of 1 that is y_1 , so we know usual Taylor series expansion, but then how do we compute y dashed of 1, y double of 1 along similar lines as it will be done for y of 1.

(Refer Slide Time: 04:28)

Handwritten notes on a blue background showing Taylor's formula of order 2 and a calculation. The text is written in black ink. In the top right corner, there is a small logo for 'CET LIT KGP' and a circled number '2'. The main text reads:

$$\text{Taylor's series of order 2}$$
$$y_1 = y^{(1)} = y_0 + h y_0' + \frac{h^2}{2!} y_0''$$

Given

$$y^{(0)} = y_0 = 0$$
$$y^{(1)} = y_0' = 1$$
$$y^{(2)} = y_0'' = 2$$
$$y^{(1)} = 0 + 1 \cdot 1 + \frac{1^2}{2!} \cdot 2 = 2$$

So, let us have a look at that. So, Taylor series of order 2, so this is y_1 , this is y_0 y_0 prime h square by y_0 double. So, given data y of 0, y dash of 0, y double of 0 therefore, y_0 , y_0 dashed, y_0 double we have, so hence y_1 can be easily computed. So, this is 0 h is 1 , y_0 dashed is 1 plus h square by 2 factorial therefore, this is 1 there 1 there two. Now, what is next to being computed? So, y_1 we have computed, now we have to compute y_1 prime, so how do we do it? So, let us write down the Taylor series of order 2 for y_1 prime.

(Refer Slide Time: 6:33)

The image shows a whiteboard with handwritten mathematical work. At the top right, there is a small logo that reads "© CET I.I.T. KGP" and a circled number "1". The main work consists of several lines of equations:

$$y_1' = y^{(1)} = y_0' + h y_0'' + \frac{h^2}{2} y_0'''$$
$$\text{given } y_0 = 0; y_0' = 1; y_0'' = 2$$
$$y''' + 2y'' + y' - y = \cos x$$
$$\Rightarrow y''' = \cos x - 2y'' - y' + y$$
$$\therefore y'''(0) = 1 - 2(2) - 1 + 0 = -4$$
$$\text{hence, } y_1' = 1 + 1(2) + \frac{1^2}{2}(-4) = 1$$

At the bottom left of the whiteboard, there is a small logo for "NPTEL".

So, y_1' is equal to y_0' plus so it is like y_1' , so let y_1' equal to z . So, then for z of 1 we write it and replace it, so same thing we are doing, so this is our expression, but this is the given data. So, in order to compute y_1' , we need y_0' triple, which we do not have, but we know that y is the solution of given ODE. So, this implies y_3 equals to minus 2 y_2 double minus y_1' plus y .

Therefore, y_3 of 0 1 minus 2 y_2 double is minus $y_1 y_0$ will be 0, so this is minus 4. Now, we are in a position to compute this one, hence this is y_0' prime is 1. So, $h y_0'$ double prime is 2 1 square by 2 y_0' triple prime, so this is $y_3 y_1'$ dash of 1 this is minus 2 and this is 2 get cancelled and this will be 1. So, we got approximation y_1' dash of 1.

(Refer Slide Time: 09:44)

$$y_1'' = y''(1) = y_0'' + h y_0''' + \frac{h^2}{2} y_0^{(4)}$$
$$y'' = \cos x - 2y'' - y' + y$$
$$y^{(4)} = -\sin x - 2y''' - y'' + y'$$
$$\therefore y^{(4)}(0) = -0 - 2(-4) - 2 + 1 = 7$$
$$\text{hence, } y''(1) = 2 + 1(-4) + \frac{1^2}{2}(7) = \frac{3}{2}$$

So, Taylor series for this, now we do not know $y^{(4)}$, but given from the ODE, we have computed. So, from here $y^{(4)}$ therefore, $y^{(4)}$ of 0 is $y^{(3)}$ of 0 just now we have computed $y^{(3)}$ of 0 minus 4 $y^{(2)}$ of 0 y' dashed, so this is 7. Hence, y'' of 0 double 2 this is $y^{(3)}$ minus 4 $y^{(4)}$ is 7, so this will be using second order Taylor series we have obtained approximations to Y of 1, y' dash, y'' of double dashed of 1. So, all that we have done is we made use of the given having known that $y(x)$ is the solution of ODE, we have computed the higher order derivatives. Suppose you have to compute $y^{(4)}$ of 1 then we differentiate this further and try to obtain the higher order of derivatives.

(Refer Slide Time: 12:41)

P2) Given the initial value problem
 $y' = x - y^2$, $y(0) = 1$, if the error
in $y(x)$ obtained from the first ~~four~~ ^{five} terms of
the Taylor's series is to be less than 0.00005, find
the value of x .

Sol. $y(x) = y(0) + x y_0' + \frac{x^2}{2!} y_0'' + \frac{x^3}{3!} y_0''' + \frac{x^4}{4!} y_0^{(4)}$

$$y_0 = 1; y_0' = x_0 - y_0^2 = 0 - 1 = -1$$

So, let us proceed further, given the initial value problem y' equals to x minus y square, $y(0)$ is 1, If the error in y of x obtained from the first five terms of the Taylor's series is to be less than 0.00005. So, let us try to understand given the initial value problem, if the error of y of x obtained from the first 4 terms of the Taylor series is to be less than, that means you obtain y of x and if the error has to be less than this then what should be the condition on x . So, first 4 terms means we have to compute up to y'''' that means y of x obtained from first 4 terms.

So, this is $y(0)$ plus x plus x square by 2 factorial plus Taylor series method first 1 2 3 4 first 5 letters make it 5, so that is plus x 4 by 4 factorial 1 2 3 4 5, first 5 terms. So, we need to compute the higher order derivatives, so $y(0)$ equals to 1, $y'(0)$ equals to $x(0)$ minus $y(0)$ square so that is 0 minus 1.

(Refer Slide Time: 16:34)

$$y'' = 1 - 2yy' \Big|_{(1,0)} = 1 - 2(1)(-1) = 3$$

$$y''' = -2(y^2 + yy'') \Big|_{(1,0)} = -2(1 + 3) = -8$$

$$y'''' = -2(2y'y'' + y'y''' + yy'''')$$

$$= -2(2(-1)3 + (-1) \cdot 3 + 1(-8))$$

$$= -2(-6 - 3 - 8) = 34$$

$$\therefore y(x) = 1 - x + \frac{3}{2}x^2 - \frac{4}{3}x^3 - \frac{7}{12}x^4$$

Then $y''(0)$ double so that is 1 minus evaluated at so this will be 1 minus 2, $y'(0)$ is 1, y' dash is minus 1 then $y'''(0)$ is minus 2, y' dash square evaluated at, so this will be 1 $y(0)$ is 1 and $y''(0)$ is 3 then $y''''(0)$ 4. So, this will be 2 y' dash is minus 1, $y''(0)$ is 3, plus y' dash is minus 1 3, so this will be therefore, y of x is we have written already $y(0)$ plus y' dash $x(0)$. So, by substituting we get 1 minus x plus 3 by 2 x square minus 4 by 3 x cube minus 7 by 12 x 4, so this is using first 5 terms. Now, if this is the case then what will be the error?

(Refer Slide Time: 24:03)

Q3 Apply Euler-Cauchy method with step size h to the IVP $y' = -y$; $y(0) = 1$

a) determine an explicit expression for y_n

b) for what values of h the sequence $\{y_n\}$ is bounded?

sol:

Euler-Cauchy method

$$y_{n+1} = y_n + \frac{h}{2} (k_1 + k_2)$$
$$k_1 = f(x, y)$$
$$k_2 = f(x+h, y+hk_1)$$

Now, problem 3 apply Euler-Cauchy method with step size h to the I V P and determine and express it expression for y_n , for what values of h the sequence y_n is bounded. So, what the method says apply Euler-Cauchy method with step size h to this initial value problem. Determine explicit for determination y_n and for what values of the sequence of h y_n is bounded. So, when we determine expression then b part is triple, so how do we proceed? So, first let us write down Euler-Cauchy method, so this is Euler-Cauchy method. Now, we have to use this method and determine the solution y_n .

(Refer Slide Time: 27:07)

For the given IVP $y' = -y$, $y(0) = 1$

$$f(x, y) = -y$$
$$\therefore k_1 = f(x_n, y_n) = -y_n$$
$$k_2 = f(x_n+h, y_n+hk_1)$$
$$= -(y_n+hk_1) = -(y_n-hy_n)$$
$$\therefore y_{n+1} = y_n + \frac{h}{2} [-y_n - (y_n-hy_n)]$$
$$= (1-h+\frac{h^2}{2})y_n$$

So, for the IVP of $x' = y$ is minus y therefore, k_1 equals this, k_2 is so this is nothing but minus y_n plus $h k_1$, this is minus y_n , k_1 is minus y_n so minus $h y_n$. Therefore, y_{n+1} is y_n plus h by 2 , k_1 is this plus k_2 , so minus y_n minus h . So, this is one coefficient here and so 1 and minus 2 get cancelled, so minus h then this is plus h^2 by $2 y_n$.

(Refer Slide Time: 29:26)

Handwritten mathematical derivation on a blue background:

$$y_{n+1} = \left(1 - h + \frac{h^2}{2}\right) y_n$$

$$y_1 = \left(1 - h + \frac{h^2}{2}\right) y_0$$

$$y_2 = \left(1 - h + \frac{h^2}{2}\right) y_1 = \left(1 - h + \frac{h^2}{2}\right)^2 y_0$$

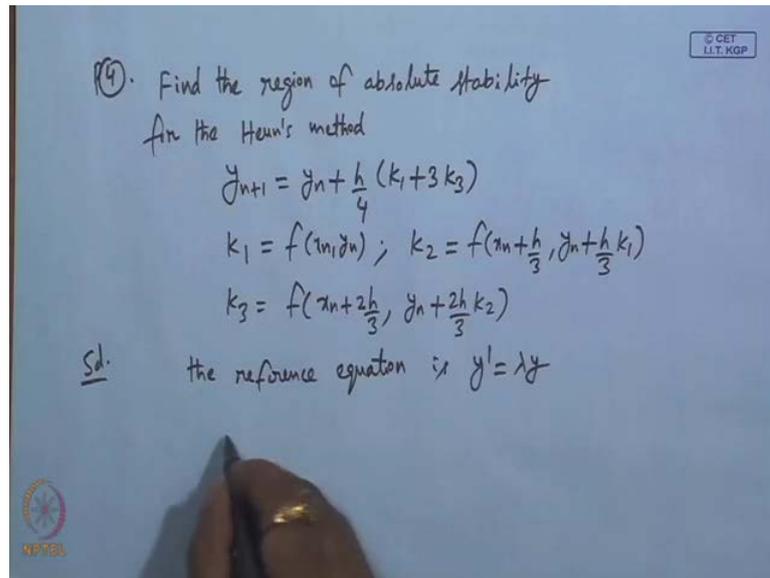

$$\vdots$$

$$y_n = \left(1 - h + \frac{h^2}{2}\right)^n y_0, \quad n = 1, 2, \dots$$

$\{y_n\}$ is bounded iff $\left|1 - h + \frac{h^2}{2}\right| \leq 1$
 $\Rightarrow \underline{0 < h \leq 2}$

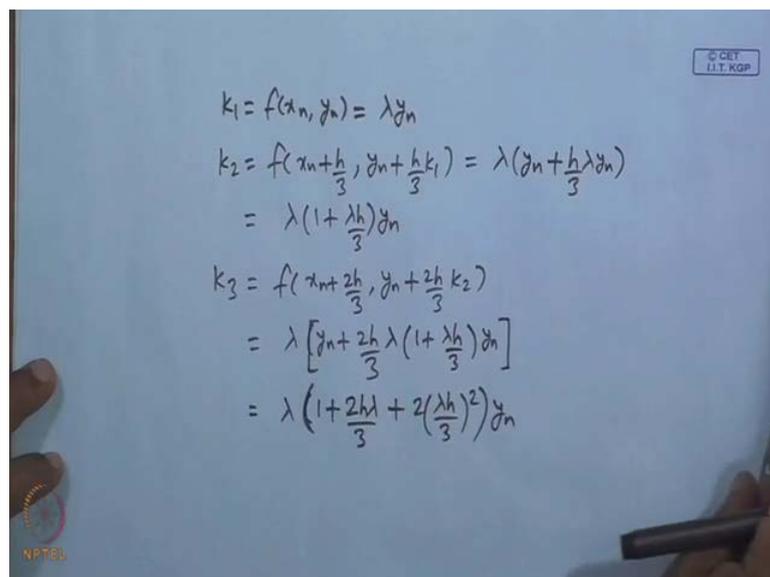

So, what did we get y_{n+1} is $1 - h$. So, y_1 is y_0 , recursively if you apply y_0 hence, y_n is y_0 , n is equal to $1, 2$. So, this is an expression so a part is done, now for b part. So, for what values of h is the sequence y_n is bounded, so this is the sequence is bounded if and if $\left|1 - h + \frac{h^2}{2}\right| \leq 1$, this implies this is a range for which the sequence is bounded. So, such methods will give an idea how to compute the boundedness of the solution and the range and the step size. So, we have simply applied on this method and then tried to determine the solution y_n explicitly and then put the condition for the boundedness.

(Refer Slide Time: 31:52)

So, let us move further, find the region of absolute stability of the Heun's method given by where k_1 is this and find the region of absolute stability of Heun's method. Now, what do we do for absolute stability, there is a reference equation so we have to consider only the corresponding reference equation. So, what will be that the reference equation is $y' = \lambda y$ so the reference equation is $y' = \lambda y$.

(Refer Slide Time: 34:25)

So, let us work out k_1 is f of x_n, y_n , which is λy_n , k_2 will be λ times y_n plus h by $3k_1$, k_1 is so this is λ plus then k_3 . So, this will be λk_2 , k_2 will be λ plus 2 by $3h$ λ plus 2 square y_n .

(Refer Slide Time: 36:40)

Handwritten mathematical derivation on a blue background:

$$\begin{aligned} \therefore y_{n+1} &= y_n + \frac{h}{4} \left[\lambda y_n + 3\lambda y_n \left(1 + \frac{2h}{3} + 2\left(\frac{\lambda h}{3}\right)^2 \right) \right] \\ &= y_n \left\{ 1 + \frac{\lambda h}{4} + \frac{3\lambda h}{4} + \frac{\lambda^2 h^2}{2} + \frac{1}{6} \lambda^3 h^3 \right\} \\ &= E(\lambda h) y_n \quad \text{where} \\ E(\lambda h) &= 1 + \frac{\lambda h}{4} + \frac{\lambda^2 h^2}{2} + \frac{1}{6} \lambda^3 h^3 \end{aligned}$$

for absolute stability, $|E(\lambda h)| \leq 1$

$$\Rightarrow \left| 1 + \frac{\lambda h}{4} + \frac{\lambda^2 h^2}{2} + \frac{\lambda^3 h^3}{6} \right| \leq 1 \Rightarrow \lambda h \in (-2.51, 0)$$

possible values: if $h = \frac{1}{2}$, $\lambda = -1$ is a stable

So therefore, y_{n+1} is y_n plus h by 4 , this method is k_1 plus $3k_3$. So, k_1 is λy_n , k_3 is this much, so $3\lambda y_n$ plus so this is simplified 1 plus λh by 4 . Now, this is exactly E of $\lambda h y_n$ where, E of λh equals 1 plus λh plus this. Now, for absolute stability, this implies λh belongs to minus 2.51 . So, it is pity tough, but one can solve it and this is the interval of absolute stability.

So, for example, if we have some possible values so for example, if h is of course, always positive so if λ is positive, so whatever may be the value so if it is beyond this then it is not administrative values. So, λ equals to say minus 1 so this gives absolute stable, so one can obtain various values.

(Refer Slide Time: 40:36)

P5 Consider the method $y_{n+1} = y_n + h f_{n+1}$ and (Backward Euler) find the region of stability.

Sol. Reference equation $y' = \lambda y$.

$$\therefore y_{n+1} = y_n + h \lambda y_{n+1}$$
$$y_{n+1}(1 - \lambda h) = y_n$$
$$\Rightarrow y_{n+1} = \frac{1}{1 - \lambda h} y_n$$
$$\therefore E(\lambda h) = \frac{1}{1 - \lambda h}$$

So, let us consider this is p 5 so consider the method $y_{n+1} = y_n + h f_{n+1}$ plus 1. So, this is almost looking like Euler, but this is called backward Euler. Consider the backward Euler method and find the region of stability. So, the method is again state forward, so the reference equation is therefore, the reference equation is this therefore, $y_{n+1} = y_n + h \lambda y_{n+1}$. So, we need to get a form, so how do we get it $1 - \lambda h$ equals y_n , therefore, E of λh is this.

(Refer Slide Time: 43:45)

$$E(\lambda h) = \frac{1}{1 - \lambda h}$$

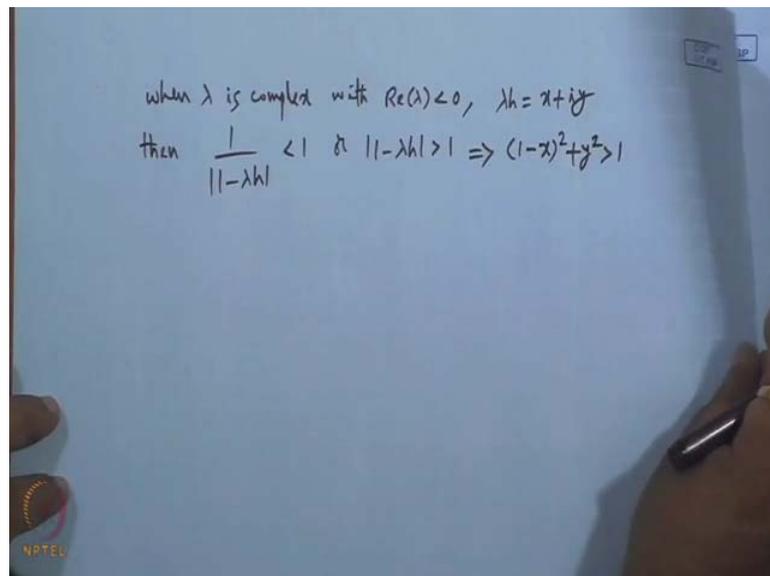

For absolute stability $|E(\lambda h)| \leq 1$

$$\Rightarrow \frac{1}{|1 - \lambda h|} \leq 1$$

when λ is real and $\lambda < 0$ then $\frac{1}{|1 - \lambda h|} < 1$ is true always. The method is absolutely stable for $-\infty < \lambda h < 0$.

Now, for absolute stability we had E of λh is $1 - \lambda h$ for absolute stability. So, we need this so this condition we have to come up with the range, so before error at the range we can argue λ is positive what happens and negative what happens like that? When λ is real and λ is negative then see if λ is negative so h is positive, if h is negative so this becomes $1 + \lambda h$. So, this 1 hour of that is then is true always therefore, the method is absolutely stable for minus infinity $\lambda h > 0$.

(Refer Slide Time: 45:56)

In the other case the λ can be complex as well, when λ is complex with real part of λ is less than 0, so λ is complex real part is this. So, this quantity is less than 1, we need or $1 - \lambda h$ greater than 1, so this gives $1 - x^2$ greater than 1, so what is this region? This is the region outside the circle, it is a intersect $1 - 0$, so this is region and radius 1. So, depending on the problem we error it different stability conditions, but for a given problem how do you come across a λ . See f is non linear here so f can be any non-linear quantity, but then the linearization says you can linearize it and then figure out what is f ?

(Refer Slide Time: 48:04)

• $y' = x^2 + y = f(x, y)$
 $\lambda = \frac{\partial f}{\partial y} = 1$

• $y' = x^2 - y^2$
 $\lambda = -2y$
about the point $(0, 1)$, then $\lambda = -2$

So for example, if y' is say $x^2 + y$ so our f of x, y then our λ is $\frac{\partial f}{\partial y}$ by $\frac{\partial}{\partial y}$, so in this case there is just 1. Suppose, y' is $x^2 - y^2$ so then λ is $-2y$. Now, suppose we would like to analyze about the point $(0, 1)$ then λ is -2 . So for example, when you use Euler method what kind of h will give us, so that the method is absolutely stable so keeping this λ in you, for this initial value problem we have to choose h such that the range of the absolute stability interval is met. So, these are some observations we have to be careful about. Now, let us look at another problem, this is RK second order.

(Refer Slide Time: 49:59)

Ⓟ Consider the Runge-Kutta second order method

$$y_{n+1} = y_n + \left(1 - \frac{1}{2\alpha}\right)k_1 + \frac{1}{2\beta}k_2$$
$$k_1 = hf(x_n, y_n)$$
$$k_2 = hf(x_n + \alpha h, y_n + \beta k_1)$$

find the region of absolute stability.

sol. $y' = \lambda y \Rightarrow f = \lambda y$
 $k_1 = h\lambda y$

Consider the Runge-Kutta second order method given by equals to y_{n+1} . Well if you take h there we need not otherwise we have to take h here this $\alpha = h\beta k_1$. So, if this is the case find the region of absolute stability, so the story is the same. Now, consider the reference equation $y' = \lambda y$ this implies this, so $k_1 = h\lambda y$ then k_2 is h .

(Refer Slide Time: 52:16)

$$\begin{aligned}
 k_2 &= h f(t_n + \alpha h, y_n + \beta k_1) \\
 &= h \lambda (y_n + \beta k_1) = \lambda h (y_n + \lambda h \beta y_n) \\
 &= \lambda h (1 + \lambda h \beta) y_n \\
 \therefore y_{n+1} &= y_n + \left(1 - \frac{1}{2\alpha}\right) \lambda h y_n + \frac{1}{2\beta} \lambda h (1 + \lambda h \beta) y_n \\
 &= \left[1 + \lambda h \left(1 - \frac{1}{2\alpha}\right) + \frac{\lambda h}{2\beta} (1 + \lambda h \beta)\right] y_n, \text{ (choosing } \alpha = \beta) \\
 &= \left[1 + \lambda h \left(1 - \frac{1}{2\beta}\right) + \frac{\lambda h}{2\beta} (1 + \lambda h \beta)\right] y_n \\
 &= \left(1 + \lambda h + \frac{\lambda^2 h^2}{2}\right) y_n
 \end{aligned}$$

So, this is h into λy_n plus, so this is $\lambda h y_n$ plus βk_1 , that will be $\lambda h \beta y_n$, so this will be 1 plus $\lambda h \beta y_n$. Therefore, this was our y_{n+1} so $y_{n+1} = y_n + k_1$, so $k_1 = \lambda h y_n$ plus 1 by βk_1 $\lambda h \beta y_n$. So, this can be written as $1 + \lambda h$, it take common 1 minus plus λh by β $1 + \lambda h \beta$.

So, from here we have obtain what is E of λh . So, consider a special case choosing $\alpha = \beta = 1$ plus at least in this case we get $1 + \lambda h$ plus into y_n . This is the special case otherwise you get a very complicated expressions, so we have to get the range of the interval will consist of α and λh .

(Refer Slide Time: 56:26)

$$\therefore E(\lambda h) = \left(1 + \lambda h + \frac{\lambda^2 h^2}{2}\right)$$

For a. stability $|1 + \lambda h + \frac{\lambda^2 h^2}{2}| \leq 1$

$$\Rightarrow \lambda h \in (-2, 0)$$

if $h = \frac{1}{4}$, $\lambda = 3$, the method is not a. stable

$h = \frac{1}{2}$, $\lambda = -2$, the method is a. stable

So, at least in this case it gets simplified therefore, E of λh is $1 + \lambda h + \lambda h^2$. So for absolute stability mod, this must be less than equal to 1, so this is satisfied and λh belongs to $[-2, 0]$. So, that means if say h is one-fourth so λ equals to say 3, the method is not absolutely stable because it is -2 . Suppose h is half and λ equals to -2 then the method is absolutely stable.

So, estimating these stability intervals is very much useful, so that there is a trade of between the λ and then step size and the internal λ depends on the given non linear function. So, may be next class we may do some more problems until then.

Thank you, bye.
