Lecture - 6
Asymptotic Properties of Entropy and Problem Solving in Entropy

In the last class, we looked at the procedure to evaluate information of a Markov source with arbitrary memory based on conditional information measures. Today, we will look at the evaluation of information of a Markov source with the arbitrary memory, based on joint information. In order to do that, let me take a simple example. Let us assume that I have a message V in form of symbols of length n .

(Refer Slide Time: 01:18)

Handwritten notes on a whiteboard:

$$V_i \rightarrow s_{i1}, s_{i2}, \dots, s_{in} \quad S = \{s_1, s_2, \dots, s_q\}$$

$$H(V) = H(s_1, s_2, \dots, s_n) \text{ bits/message}$$

$$H_N(S) \triangleq \frac{1}{N} H(V) = \frac{1}{N} \{H(s_1, s_2, \dots, s_n)\}$$

$$H_N(S) = \frac{1}{N} \sum_{i=1}^N H(s_i) = \frac{1}{N} \{NH(S)\} = H(S)$$

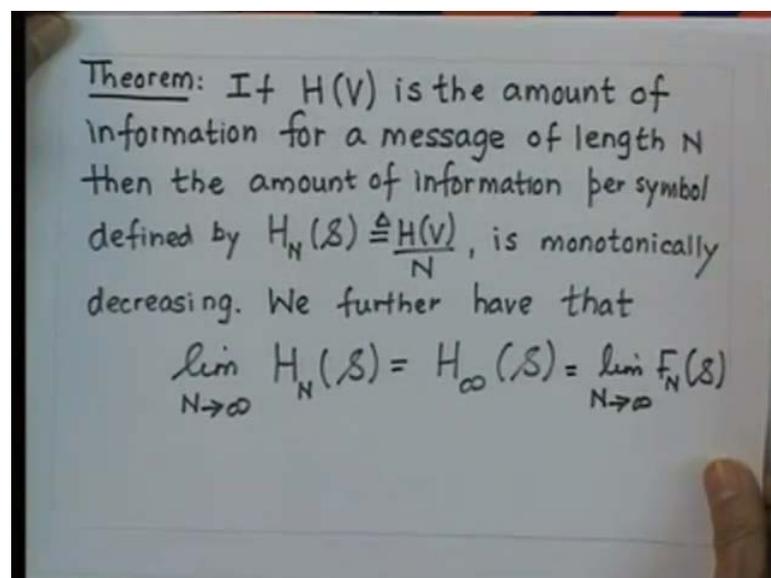

$$H_N(S) = \frac{1}{N} \left[H(s_1) + H(s_2|s_1) + H(s_3|s_1, s_2) + \dots \right. \\ \left. + H(s_N|s_{N-1}, s_{N-2}, \dots, s_1, s_2) \right]$$

$$= \frac{1}{N} \sum_{j=1}^N F_j(S)$$

Previously, we had studied messages of length one only. So, let us consider messages of length N ; this s_{i1}, s_{i2}, s_{in} each of this can come from this Markov source from this arbitrary memory, whose alphabet is from s_1 to s_q . Now, I am interested in evaluating the information, which is there in this message given by V . So, on an average the information in this message of length N can be evaluated by this expression out here, this is will be bits per message. Now, if I am interested in finding out the information per symbol than $H_N(S)$ is defined as $\frac{1}{N}$ of $H(V)$. So, we can say this is by definition and this is nothing but equal to $\frac{1}{N}$ joint information.

Now, we are also seeing last time that $H_N(s)$ is equal to this quantity. If I assume that all the symbols, which consider a message of length N are independent. In that case $H_N(s)$ turns out to be same as $H(s)$, but if the symbols in these messages are not independent, then I can write a very generic expression for $H_N(s)$, which is nothing but an average information per symbol. In that message will be given by this expression out here. That is $\frac{1}{N} \sum_{j=1}^N F_j(s)$, this we had seen last time. We are also seeing that $F_N(s)$ is a monotony decreasing function of N . Today what we will try to prove first is that $H_N(s)$ also is a monotonically decreasing function of N . In order to do that let me state the theorem first.

(Refer Slide Time: 03:51)

The theorem says if H of V is the amount of formation for a message of length N . Then the amount of information per symbol defined by $H_N(s)$ is equal to $s(V)$ by N is monotonically decreasing. This is the first result, which will try to prove. We further have that limit of N tending to infinity of $H_N(s)$ will be equal to $H_\infty(s)$ which was the entropy, which we defined for a Markov source. This is nothing but equal to limit of N tending to infinity of $F_N(s)$, so will show that both the limits are equal to $H_\infty(s)$.

(Refer Slide Time: 06:34)

Proof:

$$\begin{aligned}
 H(V) &\triangleq NH_N(\mathcal{S}) \\
 &= H(\mathcal{S}_1) + H(\mathcal{S}_2|\mathcal{S}_1) + \dots + H(\mathcal{S}_N|\mathcal{S}_{N-1}, \dots, \mathcal{S}_2) \\
 &\geq NH(\mathcal{S}_N|\mathcal{S}_{N-1}, \dots, \mathcal{S}_2) \\
 \therefore H_N(\mathcal{S}) &\geq F_N(\mathcal{S})
 \end{aligned}$$

Now

$$\begin{aligned}
 H(V) &= H(\mathcal{S}_1, \mathcal{S}_2, \dots, \mathcal{S}_N) \\
 &= H(\mathcal{S}_1, \mathcal{S}_2, \dots, \mathcal{S}_{N-1}) + H(\mathcal{S}_N|\mathcal{S}_{N-1}, \dots, \mathcal{S}_2)
 \end{aligned}$$

So, let us try to prove this theorem $H(V)$ by definition is equal to N times $H_N(\mathcal{S})$. So, this is equal to H of s_1 plus H of s_2 given s_1 plus H of s_N given s_{N-1} to s_1 . Now, we have seen last time that each of this quantity out here is related by this relationship. The additional information, which I get at is less than additional information, which I get at N minus 1. This way I can continue up to the time instant one.

So, based on this relationship, which we derived last time, which is equivalent to $F_N(\mathcal{S})$ less than equal to $F_{N-1}(\mathcal{S})$, which we have proved, that this is monotony decreasing function of N and limit of this is equal to $H(\mathcal{S})$. That was the final on top of the Markov source based on this relationship out here. I can write that this expression out here is greater than or equal to N times $H(\mathcal{S}_N|\mathcal{S}_{N-1}, \dots, \mathcal{S}_1)$. Therefore, $H_N(\mathcal{S})$, which is nothing but $H(V)$ divide by N is greater than or equal to $H(\mathcal{S}_N|\mathcal{S}_{N-1}, \dots, \mathcal{S}_1)$. That is nothing but by definition $F_N(\mathcal{S})$, this we had seen this definition of $F_N(\mathcal{S})$ is equal to this we had seen last time.

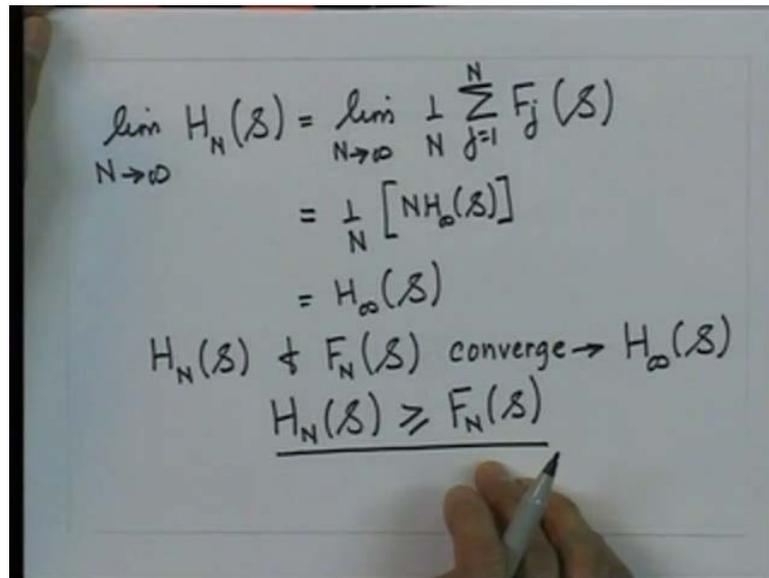

Now, $H(V)$ is equal to H of s_1, s_2 up to s_N this entropy joint entropy can be broken up as H of s_1 to s_{N-1} joint information, which I have from N minus 1 symbols plus the additional information, which I get from N symbol. So, this relationship can be written like this. Now, from this relationship and this relationship I can write N of $H_N(\mathcal{S})$ is equal to N minus 1 H of N minus 1 s plus $F_N(\mathcal{S})$.

(Refer Slide Time: 10:00)

$$\begin{aligned}
 nH_n(s) &= (n-1)H_{n-1}(s) + F_n(s) \\
 &\leq (n-1)H_{n-1}(s) + H_n(s) \quad \begin{matrix} F_n(s) \\ \leq H_n(s) \end{matrix} \\
 (n-1)H_n(s) &\leq (n-1)H_{n-1}(s) \\
 H_n(s) &\leq H_{n-1}(s) \\
 &\dots \leq H_2(s)
 \end{aligned}$$

Now, we are just seeing that $F_n(s)$ is always less than $F_n(s)$ is always less than equal to $H_n(s)$. So, from this I can write $(n-1)H_{n-1}(s) + H_n(s)$. Now, just trying to simplify this expression will get $(n-1)H_n(s) \leq (n-1)H_{n-1}(s)$, which implies $H_n(s) \leq H_{n-1}(s)$. So, I can proceed like this and show that this is less than equal to $H_1(s)$. Now, since $H_n(s)$ is always greater than equal to 0 and $H_n(s)$ monotonic decreases with n . This follows that this quantity should converge to a limit as n tends to infinity. Let us try to find out what is the value of $H_n(s)$ as n tends to infinity. So, limit of n tending to infinity of $H_n(s)$ would be limit of n tending to infinity of $1/n \sum_{j=1}^n F_j(s)$, j is equal to 1 to n .

(Refer Slide Time: 12:04)

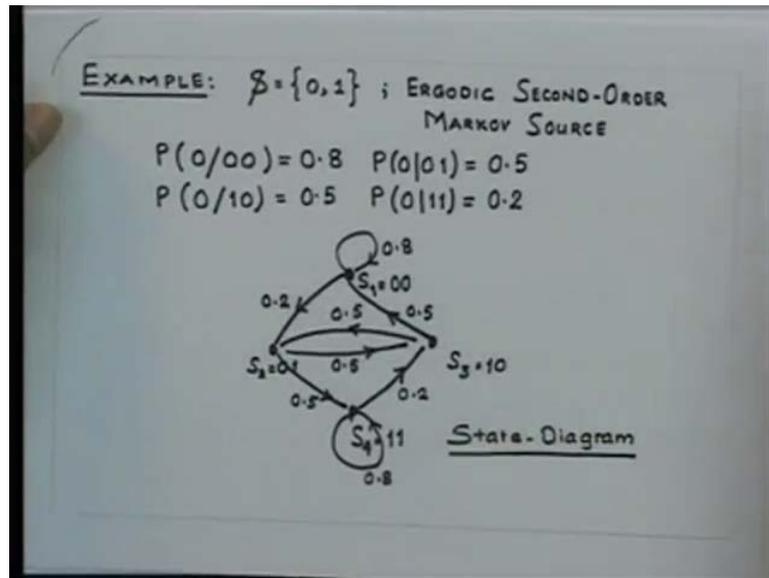

$$\begin{aligned}\lim_{N \rightarrow \infty} H_N(s) &= \lim_{N \rightarrow \infty} \frac{1}{N} \sum_{j=1}^N F_j(s) \\ &= \frac{1}{N} [N H_\infty(s)] \\ &= H_\infty(s)\end{aligned}$$

$H_N(s) \uparrow F_N(s) \text{ converge} \rightarrow H_\infty(s)$
 $H_N(s) \geq F_N(s)$

Now, we know that as N tends to infinity F_j 's because in monotonically decreasing function of N converges to H_∞ 's. Therefore, this is nothing but 1 by N n times H_∞ 's and this is equal to H_∞ 's. So, what we have proved that both H_N 's and F_N 's converge to the same limit, which is given by H_∞ 's. This is nothing but the entropy of a Markov source with arbitrary memory, but this condition is also valid, which we proved H_N 's is always less than greater than equal to F_N 's.

What it implies that H_N 's is a worst approximation to the actual amount of information H_∞ 's, but the advantage of H_N 's is its simplicity in evaluation. So, with this result let us proceed ahead and solve an example, which will help us to understand, appreciate the material, which we have covered so far. So, I will try to explain whatever we have done so far, in relation to a Markov process with the help of an example. Let us assume I have an example given here, I have a binary source 0 and 1 .

(Refer Slide Time: 14:35)

This binary source is second order Markov source. This conditional probability is have been specified probability of 0 given given 0 is 0.8 another transitional properties have been specified. We had a look at this example earlier too. Now, the first thing is to draw a straight diagram for this Ergodic second-order Markov source. To that the straight diagram for that is given as follows, we are also had a look at this said diagram earlier in the course of our lecture.

(Refer Slide Time: 15:26)

(i) How large is the amount of information of a trigram originating from this information source?

$P(000) = P(0|00)P(00)$
 $P(001) = P(1|00)P(00)$
 $P(010) = P(0|01)P(01)$
 $\quad = 1/14$
 $P(011) = 1/14$
 $P(100) = 1/14$
 $P(101) = 1/14$
 $P(110) = 1/14$
 $P(111) = 4/14$

$P(00) = P(11) = 5/14$
 $P(01) = P(10) = 1/7$
 $\frac{5}{10} \times \frac{5}{14} = \frac{4}{14}$
 $\frac{5}{14} \times \frac{2}{10} = \frac{1}{14}$

What I mean by this statement is, that if I look at the messages, which are being form this source as messages of length 3. Then what is the amount of information, which is contained in that message. So, let us try to evaluate this in order to evaluate this what I have to is basically to calculate the amount of information per trigram, the probabilities of a trigrams are determined first.

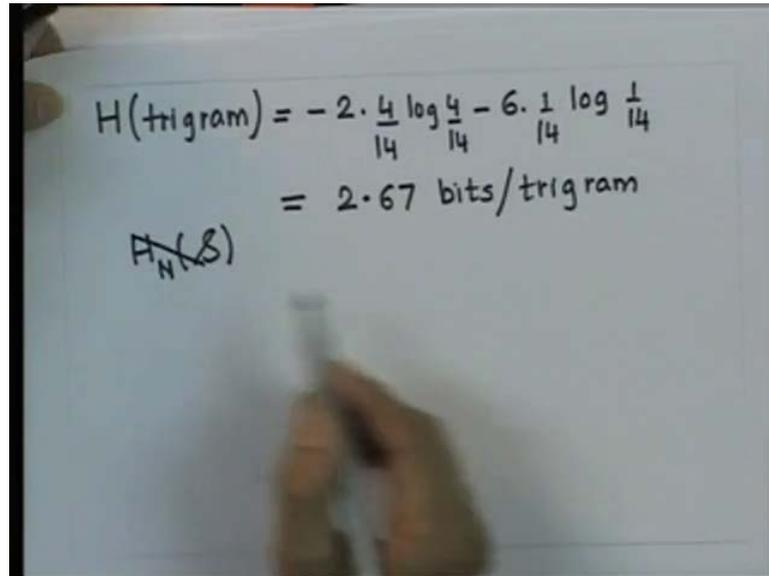

Now, in order to this what I have to find out is probability of 0 0 0. This is nothing but probability of emitting 0 given i was in the state 0 0. That is the probability of being in the state 0 0. Now, we had earlier calculated the probabilities of the states as probability of 0 0 equal to probability of 0 1 is equal to 5 by 14. Probability of 0 1 equal to probability of 1 0 is equal to 1 by 7. We have had a look at the procedure to calculate. This probability is assuming that this probability having calculate earlier. Let us try to calculate the probability of the messages of length 3.

So, the different combinations, which I can have of the messages of length 3 would be like this. So, first one is probability of 0 0 would be given by this next would be probability of 0 0 1. This would be given by what is the probability of emission of one given i was in the state 0 0 and probability of 0 0, when I am writing this probability of 0 zero 0 zero one I assume that this is the latest symbol. This is the previous symbol.

So, this is a further away from this symbol. So, to find out a probability of 0 zero 1 is that I have to find out what is the transition probability 1 given 0 zero and of being in the state 0 zero. So, I have to evaluate all this probabilities. Now, probability of 0 1 0 is again probability of zero, given i was on stage 0 one multiplied by probability of 0 1. Now, this is the quantity probability of 0 given 0 zero is 8 by 10 because 0.8 has been given to us. This is the probability, which has been given the probability of 0 zero

We have calculated that is nothing but a 5 by 14. So, this turns out to be 4 by 14. Similarly, this quantity turns out to be 5 by 14 multiplied by 2 by 10 is equal to 1 by 14 this quantity turns out to be 1 by 14. So, based on this idea I can calculate the probability is of 0 1 1 that turns out to be 1 by 14. Probability of 1 0 zero is again 1 by 14 probability of 1 0 1 is equal to 1 by 14 probability of 1 1 0 is 1 by 14. Finally, property of 1 1 1 is equal to 4 by 14. Once I have these probabilities, I can use the expression for the calculation of the entropy.

(Refer Slide Time: 20:07)

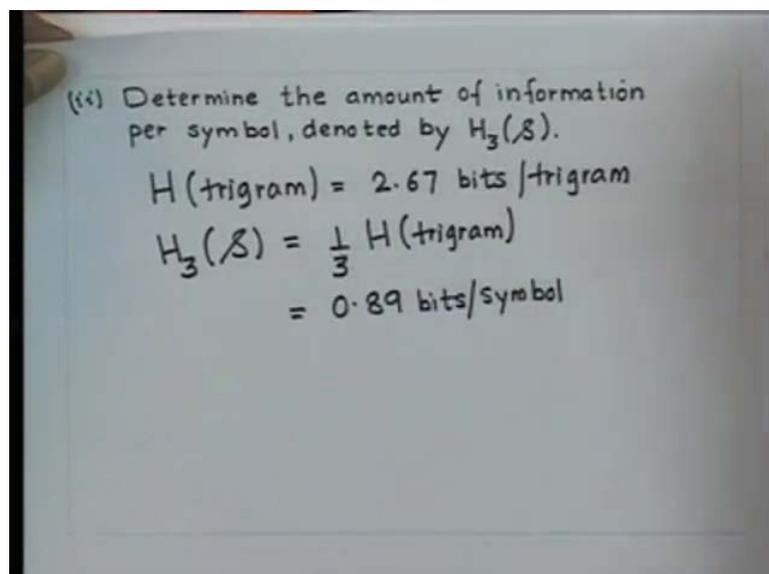

A hand-drawn diagram on a whiteboard showing the calculation of entropy for a trigram. The formula is written as $H(\text{trigram}) = -2 \cdot \frac{4}{14} \log \frac{4}{14} - 6 \cdot \frac{1}{14} \log \frac{1}{14}$, which simplifies to $= 2.67 \text{ bits/trigram}$. Below the main formula, the expression $H_3(S)$ is written and crossed out with a diagonal line.

$$H(\text{trigram}) = -2 \cdot \frac{4}{14} \log \frac{4}{14} - 6 \cdot \frac{1}{14} \log \frac{1}{14}$$
$$= 2.67 \text{ bits/trigram}$$

~~$H_3(S)$~~

Then calculate entropy or the information in the trigram as equal to minus twice 4 into 14 log of 4 by 14 minus 6 times 1 by 14, log of 1 by 14 and this turns out to be 2.67 bits per trigram. So, for the example under consideration we have for the messages of length 3. The information in those messages is 2.67 bits per message is nothing but a trigram that is symbols of length 3. Now, the next question is once I know this is basically what we are calculating is H of N s. In our case this N was nothing but now the next question is that. Once I know the message in a trigram than determine amount of information per symbol, which is denoted by $H_3 s$. Now, if I want to calculate $F_3 s$.

(Refer Slide Time: 22:03)

A hand-drawn diagram on a whiteboard showing the calculation of entropy per symbol for a trigram. It starts with the instruction: "(ii) Determine the amount of information per symbol, denoted by $H_3(S)$." Below this, the entropy of a trigram is given as $H(\text{trigram}) = 2.67 \text{ bits/trigram}$. Then, the entropy per symbol is calculated as $H_3(S) = \frac{1}{3} H(\text{trigram})$, which results in $= 0.89 \text{ bits/symbol}$.

(ii) Determine the amount of information per symbol, denoted by $H_3(S)$.

$$H(\text{trigram}) = 2.67 \text{ bits/trigram}$$
$$H_3(S) = \frac{1}{3} H(\text{trigram})$$
$$= 0.89 \text{ bits/symbol}$$

It is very simple, since I know my H of trigram was equal to 2.67 bits per trigram. This is nothing but H_V and $H_{3 \text{ s } 1}$ by $3 H$ of trigram. This is nothing but 0.89 bits per symbol. Now, the next question is I have calculated, if I were to reduce this messages of from the length 3 to length 2 then what happens to the amount of information. To answer that question let us solve this. So, next what I am interested is how large is the amount of information of a bigram. Hence, determine $H_2(S)$.

(Refer Slide Time: 23:06)

(iii) How large is the amount of information of a bigram? Hence determine $H_2(S)$.
 The probabilities of the bigrams are identical to the probabilities of the states, so that

$$H(\text{bigram}) = -2 \cdot \frac{5}{14} \log \frac{5}{14} - 2 \cdot \frac{1}{7} \log \frac{1}{7}$$

$$= 1.86 \text{ bits/bigram}$$

$$H_2(S) = \frac{1}{2} H(\text{bigram}) = 0.93 \text{ bit/symbol}$$

So, the probabilities of the bigrams are identical to the probabilities of the states and since we have calculated the probability of the states earlier, so we can say. So, that information from the bigram would be minus twice 5 by 14 log of five by 14 minus twice 1 by 7 log of 1 by seven. This turns out to be 1.86 bits per bigram this is your again H_V here are the messages of length 2. Hence, $H_2(S)$ which is nothing but half H of bigram is equal to 0.93 bit per symbol. Now, let us look at the messages of length 1. So, if I look at the messages of length one then how large is which $H_1(S)$ to calculate.

(Refer Slide Time: 25:12)

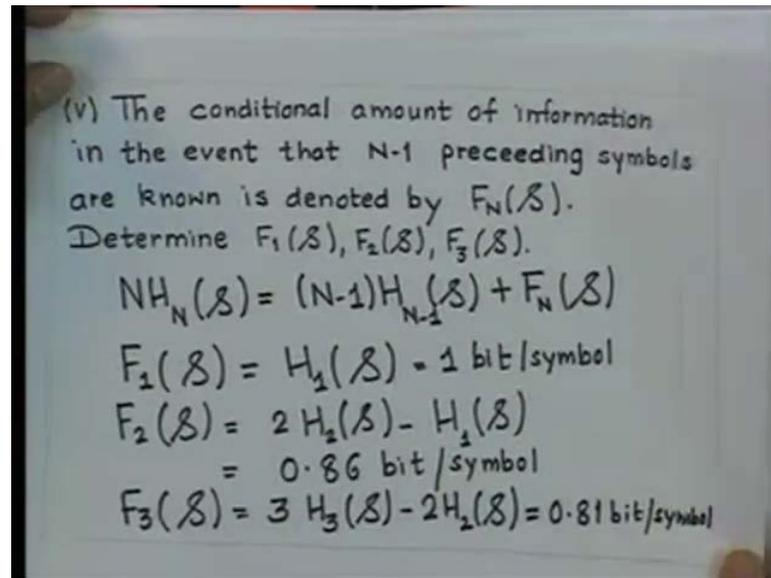

(iv) How large is $H_1(S)$?
 $P(0)$ and $P(1)$
 $P(0) = P(1) = \frac{1}{2}$
 $H_1(S) = -\frac{1}{2} \log \frac{1}{2} - \frac{1}{2} \log \frac{1}{2}$
 $= 1 \text{ bit/symbol}$

$H_3(S)$	$H_2(S)$	$H_1(S)$
0.89	0.93	1
$F_1(S)$	$F_2(S)$	$F_3(S)$

This I should know the probabilities of P_0 and P_1 . Now, once I know the probability of 0 and probability of 1, I can calculate H_1 s we have seen basically how to calculate the probability of 0 and probability of 1 for this example earlier. So, we had seen that probability of 0 is equal to probability of one and that turns out to be equal half. So, from this I get H_1 s is equal to minus half log minus half minus log half and that is equal to 1 bit per symbol.

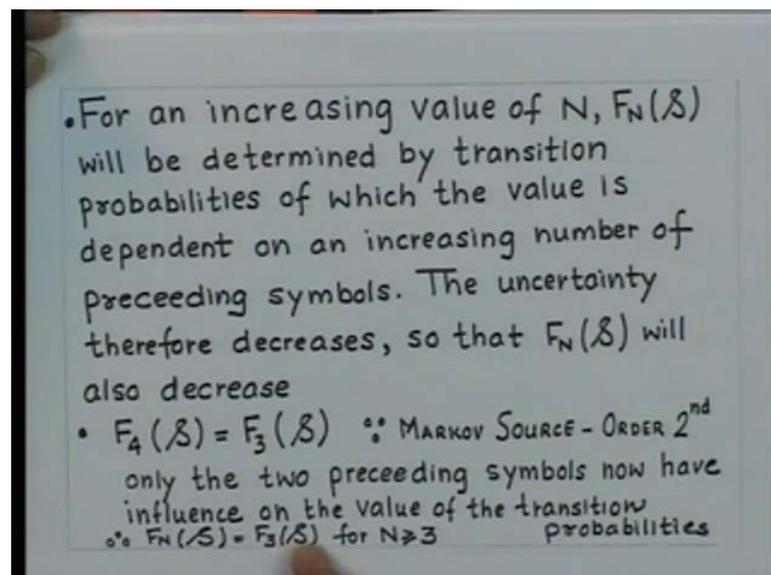

Now, we have calculated H_3 s H_2 s and H_1 s the value of H_3 s we got was 0.89 bits per symbol value of H_2 s. We got was 0.93 bits per symbol and value of H_1 was 1 bit per second 1 bit per symbol. So, what this means that as I keep on increasing N the value monotonically decreases from 1 I have reached up to 2.89. So, the final limit of H_3 of H_N s would be H_{∞} s. Now, if I were interested in to calculate F_1 s F_2 s and F_3 s, let us try evaluate this. So, the condition amount of information in the event that N minus 1 preceding symbols are known is denoted by F_N s.

(Refer Slide Time: 27:27)

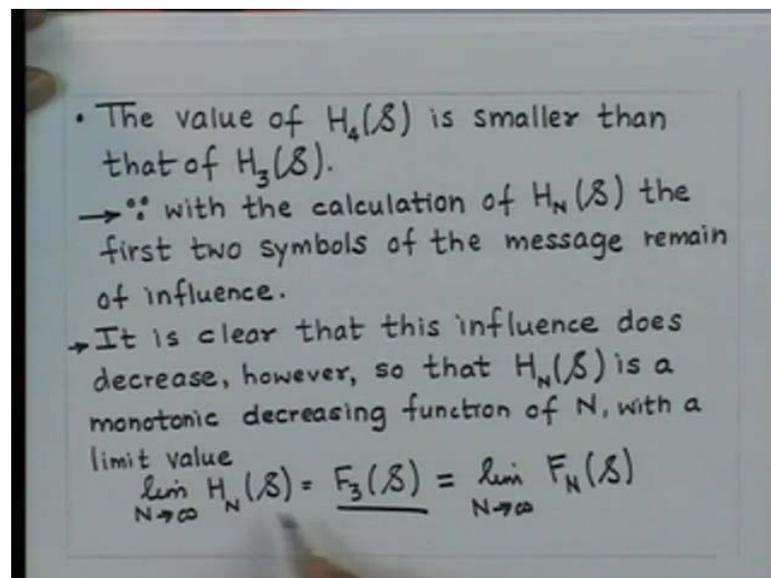

So, what I am interested is to determine F_1 s F_2 s and F_3 s we have derived that NH_N sis equal to n minus one H_N minus 1 s plus F_N s. Now, if I want to calculate F_1 s, since I know H_1 from F_1 s is nothing but H_1 s. That is nothing but one bit per symbol F_2 s from this relationship I will get as twice H_2 s minus H_1 s. Now, H_2 s and H_1 s I have calculate earlier. So, this turns out to be 0.86 bit per symbol. Finally, my F_3 s is equal to thrice H_3 s minus twice H_2 s. This comes out to be 0.81 bit per symbol.

(Refer Slide Time: 29:45)

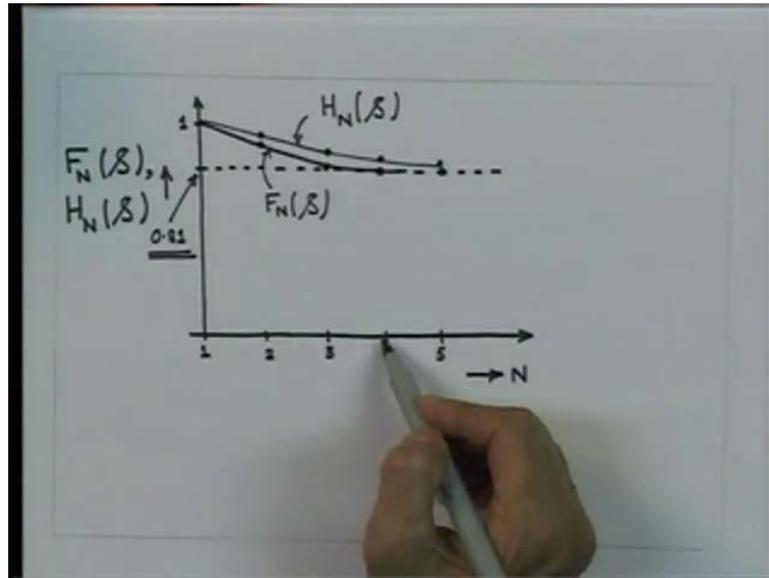

Now, what we have observed that for an increasing value of N F_N s will be determined by the transition probabilities, of which the value is dependent on an increasing number of preceding symbols. So, the uncertainty therefore decreases, therefore F_N s will also decrease. Now, in our case if you try to calculate F_4 s F_4 s will turn out to be same as F_3 s because Markov source is order second. So, the only two only the two preceding symbols, now have an influence on the value of the transition probabilities. Therefore, F_N s will be equal to F_3 s for N greater than equal to 3. Now, another interesting result is F_N s does not change beyond F_3 s, but what happens to H_4 s? if you look at H_4 s calculation.

(Refer Slide Time: 31:04)

Then you will find that the value of H_4 s is smaller than that of H_3 s, because with the calculation of H_N s the first two symbols of the message remain of influence. It is clear that this influence does decrease however. So, that H_N s is a monotonic decreasing function of N with a limit value. So, if you take the limit of H_N s N tending to infinity you will get as same as F_3 s. Because, F_3 s is nothing but limit of N tending to infinity of F_N s, because our source is the second order Markov source F_N s is for N greater than or equal to 3 is same as F_3 s. Now, if you plot the values of H_N s and F_N s as function of N , what you will get is this graph.

(Refer Slide Time: 32:19)

It is interesting to examine this graph on the x-axis I have increasing value of N on the y-axis I have plotted $F_N(s)$ or $H_N(s)$. If you look at the plot of $F_N(s)$ for N equal to 1 we found out to value to be of $f_n F_1 s$ was 1 for $F_N(s)$ for N equal 2 was lower than that. For F_3 was still lower, but $F_1 s f$ is all stabilised the value of F threes, but this is not true of $H_N(s)$. $H_N(s)$ goes monotonically decreasing function, but as I keep ongoing beyond N greater than 3. You will find that $H_N(s)$ keeps on decreasing. Finally, it approaches the value of $F_3 s$ and that is equal to 0.81. So, what I would say that entropy of this source, which we had considered is 0.81 bits per symbol. Let us take another example to understand the concepts in a much better way.

(Refer Slide Time: 33:34)

Assume that the various values of $F_j(\beta)$ are known for 26 different symbols

$F_1 = 4.15$	then $H_1 = F_1$	$= 4.15$
$F_2 = 2.99$	$H_2 = \frac{1}{2}(F_1 + F_2)$	$= 3.75$
$F_3 = 2.56$	$H_3 = \frac{1}{3}(F_1 + F_2 + F_3)$	$= 3.23$
$F_4 = 2.20$	$H_4 = \frac{1}{4}(F_1 + \dots + F_4)$	$= 2.98$
$F_5 = 1.95$	$H_5 = \dots$	$= 2.77$
$F_6 = 1.72$	$H_6 = \dots$	$= 2.60$
$F_7 = 1.63$	$H_7 = \dots$	$= 2.46$
$F_8 = 1.60$	$H_8 = \dots$	$= 2.35$

$H_\infty(\beta) = 1.50 \text{ bits/symbol}$ $\max H(\beta) = \log 26 = 4.70 \text{ bits/sym}$

Assume that the various values of F_j are known for 26 different symbols. This could be an example of English literature. So, let us assume that I know F_1 , so that will be equal to 4.15 bits. If I can calculate F_2 , which I am calculation of all this $F_1 F_2 F_3$ is based on the conditional information measure. So, F_2 if I can calculate if I know it is 2.99. I can calculate H_2 , which is equal to $\frac{1}{2}(F_1 + F_2)$ and that turns out to be 3.75. So, I can keep on calculating this $F_1 F_2 F_3 F_4$ up to F_8 .

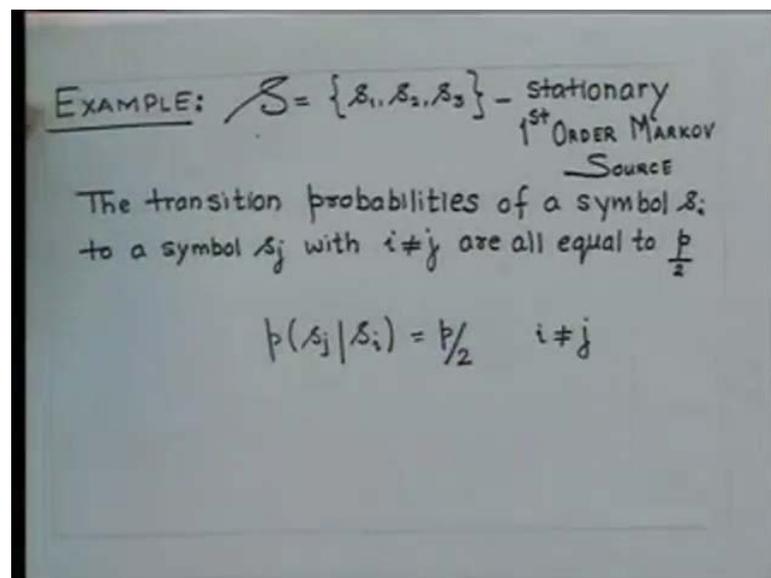

Similarly, I can calculate the values for H_8 from F , if you look at these values of F_n and H_n there is an interesting result. You will find that always H_n is larger than f_n that is the one-point, which you have to notice another is f_n is always a monotonically decreasing function of N . Similarly, you will find that H_n is monotonically decreasing function of N . Now, if you look at the way these f_n decreases f_n decreases much faster than H_n . When I reach F_8 the value for entropy turns out to be 1.60 bits per symbol, whereas 2.25 bits per symbol.

If you continue this process then you will find H_∞ stabilises or converges to a value of 1.50 bits per symbol. H_n will also converge to the same value one-point bits per symbol, but the convergence rate will be slower than that for f_n . If I were to find out what is the maximum value, which I can get of an information from this source, which consist of 26 different symbol the value will be obviously equal to \log of, 26 that will

happen. I assume the symbols are all independent and that turns out to be 4.7 bits per symbol.

What is to what I want to convey from this example is that if I take a source, which consist of 26 different symbols. Then the entropy of that source based on the assumption that all the symbols are I will get that entropy to be equal to 4.7 bits per symbol, but if I look at that source with a memory. Then the entropy turns out to be much lower than 4.70 bits. It is equal to 1.5 bits per symbol. So, there is a lot of discrepancy between these two entropy. Now, to get a better feel will take one more example before we conclude our discussions on the modelling of these sources, from the information point of view. Let us take another example.

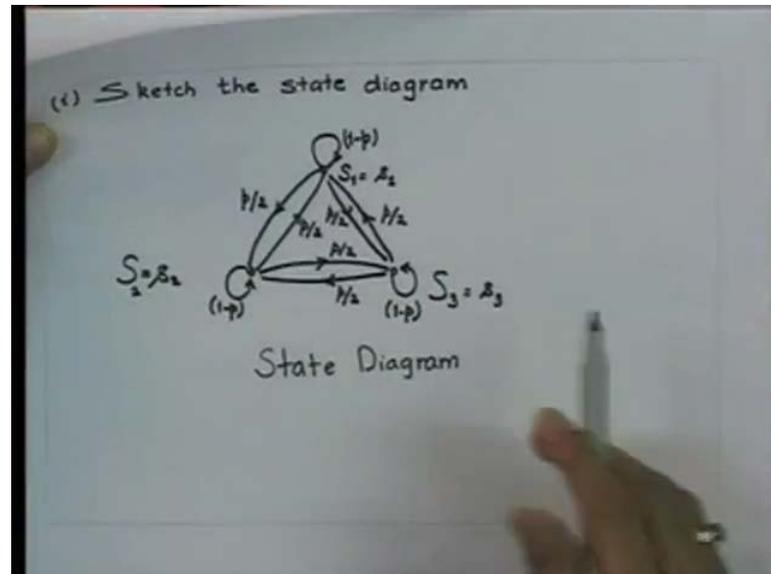

(Refer Slide Time: 37:35)

Let me assume that I have a source, which emits three symbols $s_1 s_2 s_3$. This source is a stationary and I also assume that this source is a first-order Markov source. It has been given to me that the transition probabilities of a symbol s_i to a symbol s_j with i not equal to j are all equal too $\frac{p}{2}$, p is a variable. So, what it means is that probability of s_j given s_i is equal to $\frac{p}{2}$ for i not equal to j . Now, let us try to calculate the different values for information measures, which we have studied so far. The first thing that is to be done before we do the calculation is to draw the state diagram for this source. The state diagram for the source will give us all the information, which is

essential for us to calculate all the transition probabilities. So, if I take the state diagram for this would be something like this

(Refer Slide Time: 39:12)

So, the state diagram would be given by this, this is the state diagram for source under discussion. Since, we have this source, which is a Markov source of order one. There are three symbols we have three states this three states are identical to the three symbols. So, s_1 is equal to s small s_1 capital S_2 , which denotes the state's is same as the symbol s_2 . The third state S_3 is identical to the symbol s_3 . Now, it has been given to us that probability of s_j given to s_i is equal to $p/2$ for $i \neq j$. So, if I take an example for this state then the probability going from this to this is $p/2$ and from here to here is $p/2$.

So, the probability of being in the same state would be calculated by addition of this $p/2$ plus $p/2$, that comes out to p $1 - p$ would be the probability of remaining in the state. So, similarly I can calculate for state s_2 and s_3 and this would be the state diagram, which I get for source under discussion. Next, is basically what I am interested is to calculate the probabilities of the symbols s_1 s_2 and s_3 . Now, since the state's and the symbols in this example are the same calculation of the probabilities of the symbol is equivalent to calculation of the probabilities of the state's s_1 s_2 and s_3 . We had seen how to do that let us try to calculate these probabilities.

(Refer Slide Time: 41:22)

(ii) Determine the probabilities of the symbols s_1, s_2 and s_3

The probabilities of s_1, s_2 and s_3 follow from the eqns

$$P(s_1) = P(A_1)P(s_1|A_1) + P(A_2|A_1)P(s_1|A_2) + P(A_3|A_1)P(s_1|A_3) \checkmark$$
$$P(s_2) = P(A_1|A_2)P(s_2|A_1) + P(A_2|A_2)P(s_2|A_2) + P(A_3|A_2)P(s_2|A_3) \checkmark$$
$$P(s_3) = P(A_1|A_3)P(s_3|A_1) + P(A_2|A_3)P(s_3|A_2) + P(A_3|A_3)P(s_3|A_3) \checkmark$$
$$P(A_1) + P(A_2) + P(A_3) = 1 \checkmark$$

$\therefore P(s_1) = P(s_2) = P(s_3) = 1/3$

• symmetry of the state diagram suggests that each state will occur with equal probability

So, the probabilities of symbols s_1, s_2 and s_3 or in other words the probabilities of the state capitals one capital s_2 and s_3 follow from this equation probability of s_1 would be, what is the probability of emission of s_1 , when I am state s_1 and multiplied by the probability of the state s_1 itself. Plus, what is the probability of emission of s_1 when I am state s_2 multiplied by probability of s_2 itself.

So, this would be the expression, which I get for calculation of the probability of the symbol s_1 . In this case it is equivalent to calculation of the probability of the state s_1 that is capital s_1 . Similarly, this equation follow for symbol s_2 and symbol s_3 . I know that probability of s_1 plus probability of s_2 plus probability of s_3 is equal to 1 Therefore, if I substitute this values if I solve all this equation, what I will get is this result probability of s_1 is equal to probability of s_2 is equal to probability of s_3 is equal to 1.

Now, because of the symmetry of the state diagram this result was expected. So, the symmetry suggests that each state will occur with equal probability. Now, during the course of a study of Markov source. We also talk about the information associated with the arbitrary transition. In order to understand that concept in a better way, let us try to find out the amount of information with respect to an arbitrary transition for this example under discussion.

(Refer Slide Time: 43:40)

Amount of information with respect to an arbitrary transition?

$$\begin{aligned}
 H(S_2/S_1) &= - \sum_{i=1}^3 \sum_{j=1}^3 p(s_i, s_j) \log p(s_j/s_i) \quad \left(\begin{array}{l} s_j = s_i \\ s_i \in S_1 \end{array} \right) \\
 &= - \sum_{i=1}^3 \sum_{j=1}^3 p(s_i) p(s_j/s_i) \log p(s_j/s_i) \\
 &= \sum_{i=1}^3 p(s_i) \left[- \sum_{j=1}^3 p(s_j/s_i) \log p(s_j/s_i) \right] \\
 &= 3 \cdot \frac{1}{3} \left[- 2 \frac{p}{2} \log \frac{p}{2} - (1-p) \log (1-p) \right] \\
 &= p - p \log p - (1-p) \log (1-p) \text{ bits/symbol}
 \end{aligned}$$

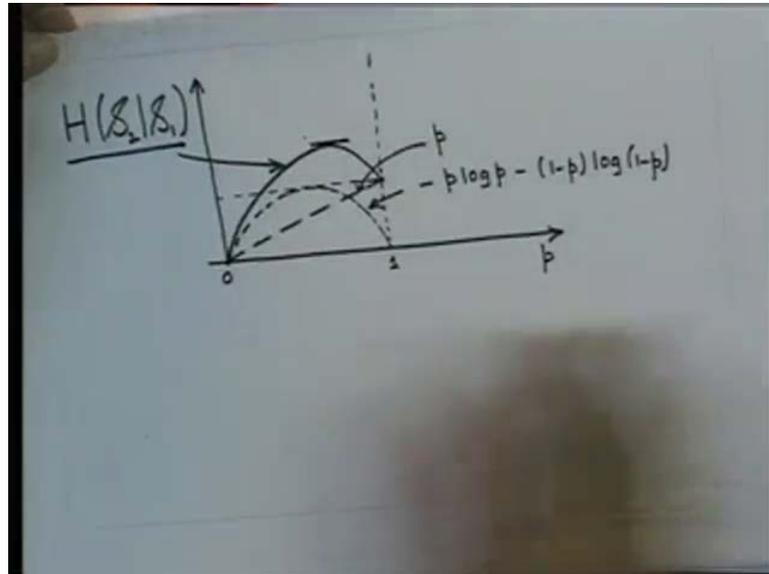

So, I am interested in the calculation of information with respect to an arbitrary transition. What I mean by that I am interested in calculating average information of s_2 given s_1 in the light of our earlier discussion this s_j is equivalent to s_{2j} and s_i is equivalent to s_{1i} . So, by definition H of s_2 given H_1 would be probability of $s_i s_j$ joint probability multiplied by what is the information, which I get when there is a transition from s_i to s_j . The amount of information, which I get from one transition from one particular transition s_i to s_j is minus log of p_{s_j} given s_i and the average value would be this.

So, if I try to simplify this value I will get as this is equal to probability of s_i probability of s_j given s_i log of probability of s_j given s_i . Now, this I can simplify as I can remove probability of s_i outside the bracket log of probability s_j given s_i this can be simplified. Because, probability of s_i 's are all equally probable three times $\frac{1}{3}$ by $\frac{1}{3}$ minus $2p$ by $2 \log$ of p by 2 minus $1 - p \log$ of $1 - p$. This is a value, which I get when I am in a particular state. Since, all the probabilities of the states are probable will just multiply by 3.

If I simplify this expression it turns out to be $p - p \log p - (1-p) \log (1-p)$ bits per symbol. If you plot this the plot of this expression as a function of p can be, this is familiar expression, which we get, this is the entropy function we have. So, this also entropy of a binary source, this is this I can plot as a straight-line. So, entropy

the amount of information with respect an arbitrary transition is sum of two functions. This is entropy function another is a linear function.

(Refer Slide Time: 47:20)

So, we can plot this as this would be the result for my entropy function. That is nothing but minus $p \log p$ minus $(1-p) \log (1-p)$. This value will range from 0 to 1 and this will be my p . So, my H of s_2 given s_1 would be the sum of this and that will turn out to be something like this. So, if you look at this additional information, this is the graph of this. Now, this graph shows that there is some kind there is a peak out here let us try to evaluate what is the value of this maximum? What is a maximum value which this achieves? For what value of p it achieves? So to determine the value of p for which this amount of information, that is s_2 H of s_2 given s_1 achieves a maximum it is not very difficult.

(Refer Slide Time: 49:23)

(iv) Determine the value of 'p' for which this amount of information, i.e. $H(S_2|S_1)$ achieves a maximum.

$$\frac{dH(S_2|S_1)}{dp} = 0$$

$$\frac{d}{dp} [p - p \log p - (1-p) \log (1-p)] = 0$$

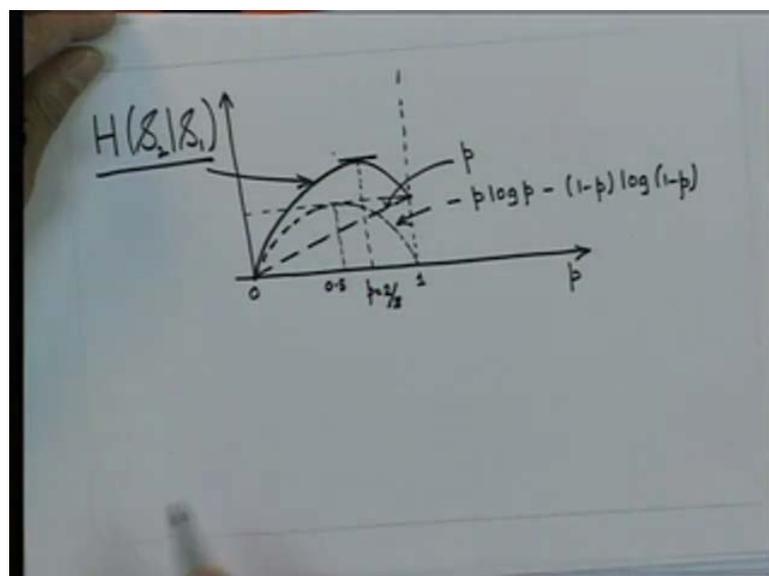

$$\Rightarrow \left[1 - \frac{1}{\ln 2} - \log p + \frac{1}{\ln 2} + \log (1-p) \right] = 0$$

$$\Rightarrow \log \left(\frac{1-p}{p} \right) = -1 \quad \Rightarrow \frac{p}{1-p} = 2 \quad \Rightarrow \underline{\underline{p = \frac{2}{3}}}$$

$$\Rightarrow \log \left(\frac{p}{1-p} \right) = 1$$

To determine the value of p for which this amount of information achieves a maximum is given by derivative of H of s 2 given H 1 s 1 is equal to 0. Now, let us take the derivative of it p minus p log p minus 1 minus p log of 1 minus p is equal to 0. This implies derivative of this is one derivative of p log p will be 1 by log 2 minus log p plus derivative of this quantity plus log of 1 minus p. This implies that log of 1 minus p upon p is equal to minus 1, which implies log of p over 1 minus p is equal to 1. Therefore, this implies that p over 1 minus p is equal to and this implies that p is equal to 2 by 3. So, the maximum value of this a value at which the maximum will occur.

(Refer Slide Time: 51:20)

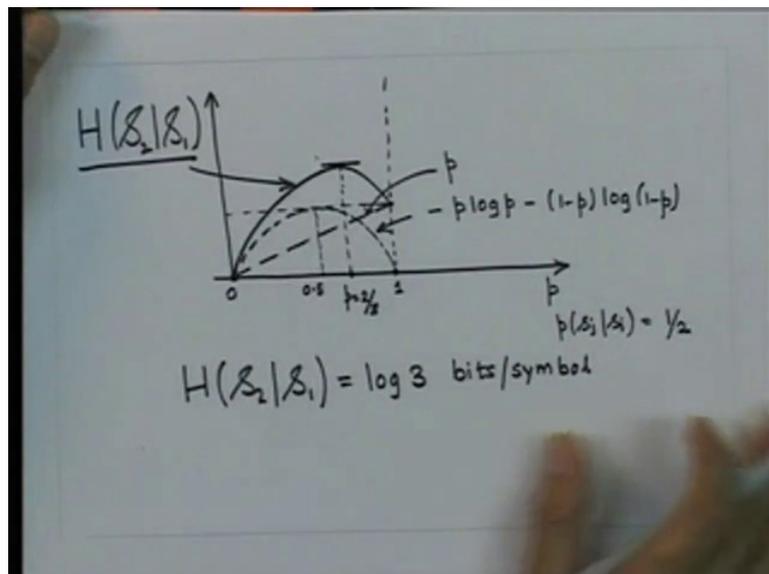

So, in this graph this maximum value will occur for p equal to $\frac{2}{3}$, this occurs at 0.5. Now, what is the maximum value? If we calculate that, maximum value I have to evaluate that expression for p equal to $\frac{2}{3}$.

(Refer Slide Time: 51:42)

$$\begin{aligned}
 H(S_2|S_1) &= \frac{2}{3} - \frac{2}{3} \log \frac{2}{3} - \frac{1}{3} \log \frac{1}{3} \\
 \text{Maximum} &= \log 3 \\
 &= \underline{1.58 \text{ bits/symbol}}
 \end{aligned}$$

If I substitute that I get $\frac{2}{3} \log$ and this turns out to be $\log 3$. This is equal to 1.58 bits per symbol. So, this is the maximum value, which I get for this quantity. This is the arbitrary transitions, now let us look at this graph. If you look at this graph H_2 s H of s_2 given s_1 for p equal to 0 I get this value to be 0.

(Refer Slide Time: 52:59)

Now, this is expected, because at this point p equal to 0 the source remains in the same state. Therefore, there is no uncertainty and therefore, the amount of information is 0. When p is equal to 1 the source has an equal chance of coming into one of both other states from any given state, because probability of s_j given s_i is equal to half in that case. In that case the information the transition information will be 1 bit.

Now, when p is equal two third every transition has the same probability of occurring. Therefore, the source behaves as if there are three independent symbols, what it means? If a previous symbol is given the uncertainty is not reduced. Therefore, H of $s_2 s_1$ turns out to be same as then copy of the source, when the source symbols are independent and that is $\log 3$ bits per symbol.

So, with this we complete our discussions about the modelling of the sources. From information point of view, we have looked at different types of sources, sources with which are memory less. That is zero memory and the sources, which have memory. In that category we have considered a Markov source of arbitrary order. We have also looked at the calculations of the information for this source. Now, with this base we will go ahead and look at coding aspect for these sources.
